Introduction

Pancreatic cancer is among the most lethal forms of metastasis and the large majority of these are exocrine in nature. Pancreatic ductal adenocarcinoma (PDAC), an exocrine neoplasm, is the most common and aggressive form of this disease. Lack of effective treatment options is one of the many contributors to mortality. To study PDACs, human tumor tissue grown in 2D culture conditions does not support growth of non-transformed cells. Therefore, 3D models are being explored such as neoplastic pancreatic organoids that better mimic in vivo physiology and are thought to be better predictors for compound profiling. Corning® Matrigel® matrix has been the gold standard for organoid cultures providing the necessary physiological milieu to support these 3D structures. Here, we evaluated growth of human pancreatic ductal tumor organoids using Corning Matrigel matrix-3D plates. We found that these pre-coated, high throughput formats were convenient and easy to use as Matrigel matrix was already pre-dispensed into each well. The Matrigel matrix-3D plates are potential tools for drug discovery efforts using organoids as demonstrated by the ability to support human pancreatic organoid cultures.

Materials and Methods

Human pancreatic ductal adenocarcinoma organoids (hT3) were generated from tissues of pancreatic cancer patients in the laboratory of Dr. Tuveson, M.D.1 The Tuveson lab has established a solid platform to generate organoid models from normal and neoplastic murine and human pancreas tissues2. The pancreatic organoids can be rapidly generated from resected tumors and biopsies, surviving through the cryopreservation process and exhibiting ductal- and disease stage-specific characteristics1,2. This specific organoid line, hT3 has always been maintained in 3D cell culture conditions and never manipulated using 2D methods.

To test the Matrigel matrix-3D plates (Corning 356256) a cell titration was performed using disaggregated hT3 organoids and seeded at different cell densities (0 to 10,000 cells/well) following manufacturer’s instructions for the ‘overlay’ method, with minor modifications. The experiments were conducted using 7 replicates per each condition for a period of 5 days of total incubation. The 3D organoids were monitored using bright-field microscopy to visualize the formation of spheres over time. The Matrigel matrix-3D plates used were a 384-well, black/clear square bottom format pre-coated with Matrigel matrix in each well. The plates were incubated prior to seeding the cells to polymerize the Matrigel matrix.

Cells were grown in human complete feeding media containing supplements and growth factors specially formulated for human organoids as previously described2. Shown below is an outline of the protocol that was followed:

- Thaw Corning Matrigel matrix-3D plates for ≥6 hours at 4°C prior to use.
- Polymerize Matrigel matrix by incubating the microplates for 1 hour at 37°C prior to cell seeding. This results in gelation of the matrix layer.
- Seed cells onto the polymerized Matrigel matrix by carefully adding 25 µL/well of cell suspension in the growth media, taking care to not disturb the gelled layer of Matrigel matrix.
- Incubate culture in a humidified incubator at 37°C for a period of 5 days and image as needed.
- 96 hours post-cell seeding, add 25 µL/well of 3D CellTiter-Glo® reagent (Promega), and incubate for 60 minutes at room temperature.
- Read luminescence.

Results and Discussion

We observed human pancreatic organoids (hT3) formation within 48 hours of plating using standard bright-field microscopy with 4X and 10X objectives as shown in Figure 1. It also appears that the number of organoids per well was proportional to initial cell seeding density.

Figure 1. Assessment of 3D sphere formation of the hT3 organoids seeded at different cell densities in Corning Matrigel matrix-3D plates using 4X and 10X objective at different time points. Bar scale in lower right is 100 µm.
Conclusions

- Corning® Matrigel® matrix-3D plates were able to support pancreatic organoid culture.
- The Corning Matrigel matrix-3D plates were able to support a homogenous assay format, wherein both the organoid culture and end-point viability read out (luminescence) were achieved simultaneously.
- The Z’ values achieved using these plates show that they can support a robust HTS assay format.

Acknowledgments

We thank Hervé Tiriac at UCSD Moores Cancer Center and David Tuveson at Cold Spring Harbor Laboratory for providing the organoids and the conditioned media to grow the organoids.
